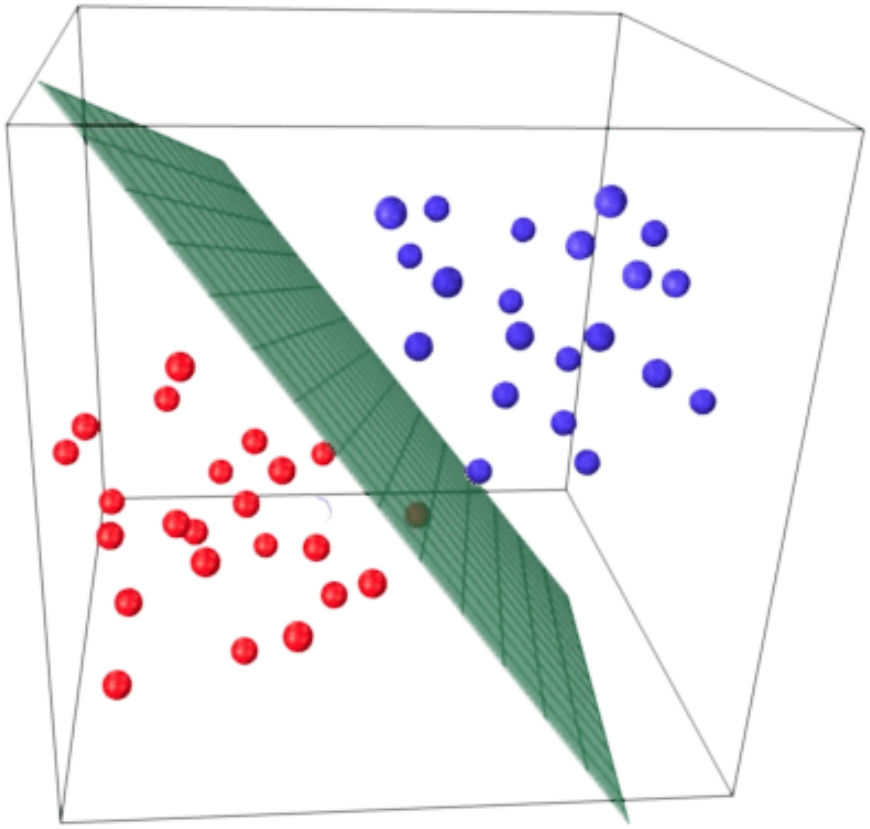
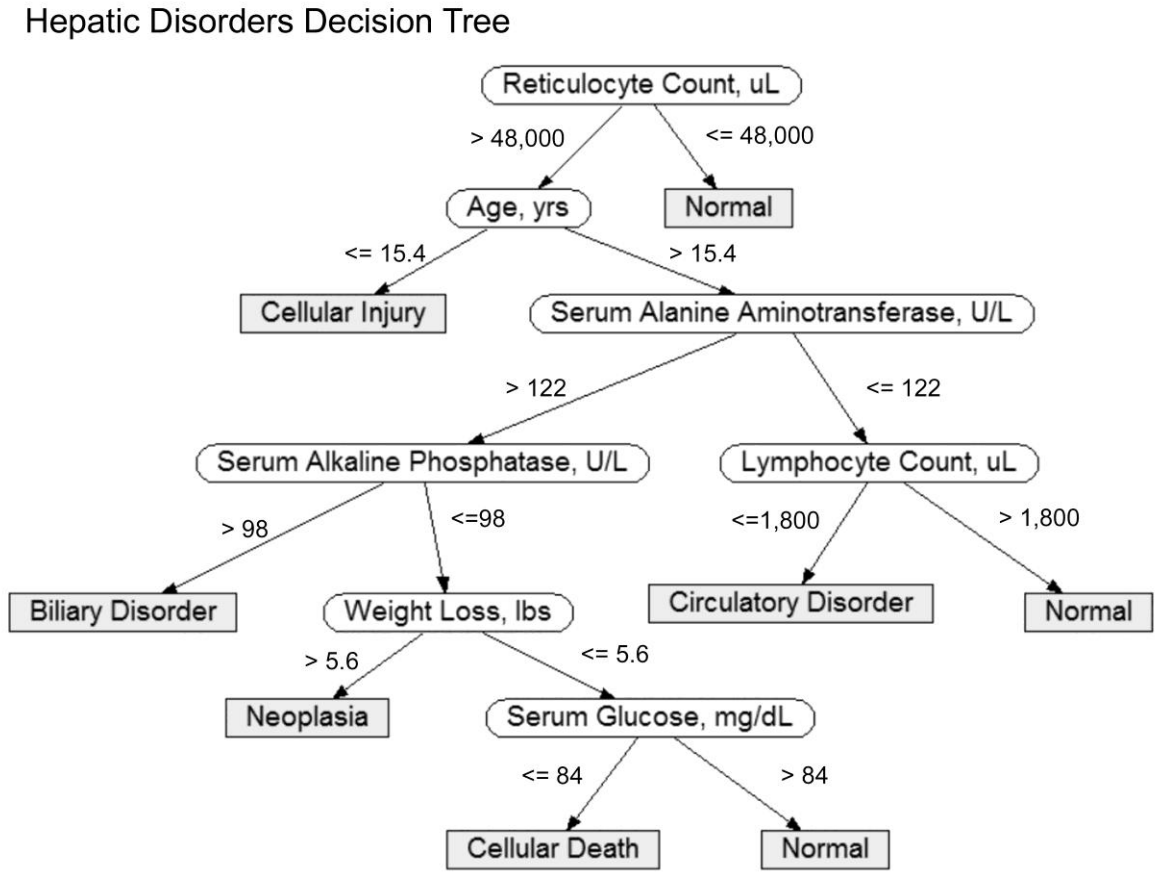
Previously: Reliance on Linear Layers

- Linear models
  - Linear regression, logistic regression, softmax regression
  - Classification: Decision boundary is defined by
    $$w_1 x_1 + w_2 x_2 + \cdots + w_d x_d + b = 0$$
  - Note: Combination of ***every*** feature x_i
    - Not necessarily how humans make decisions
    - Can be hard to understand why a prediction was made
- Neural networks
  - Linear layers are core building blocks
    - This is why MLPs are also called “fully connected” networks
  - Final decision boundary is linear function of learned features



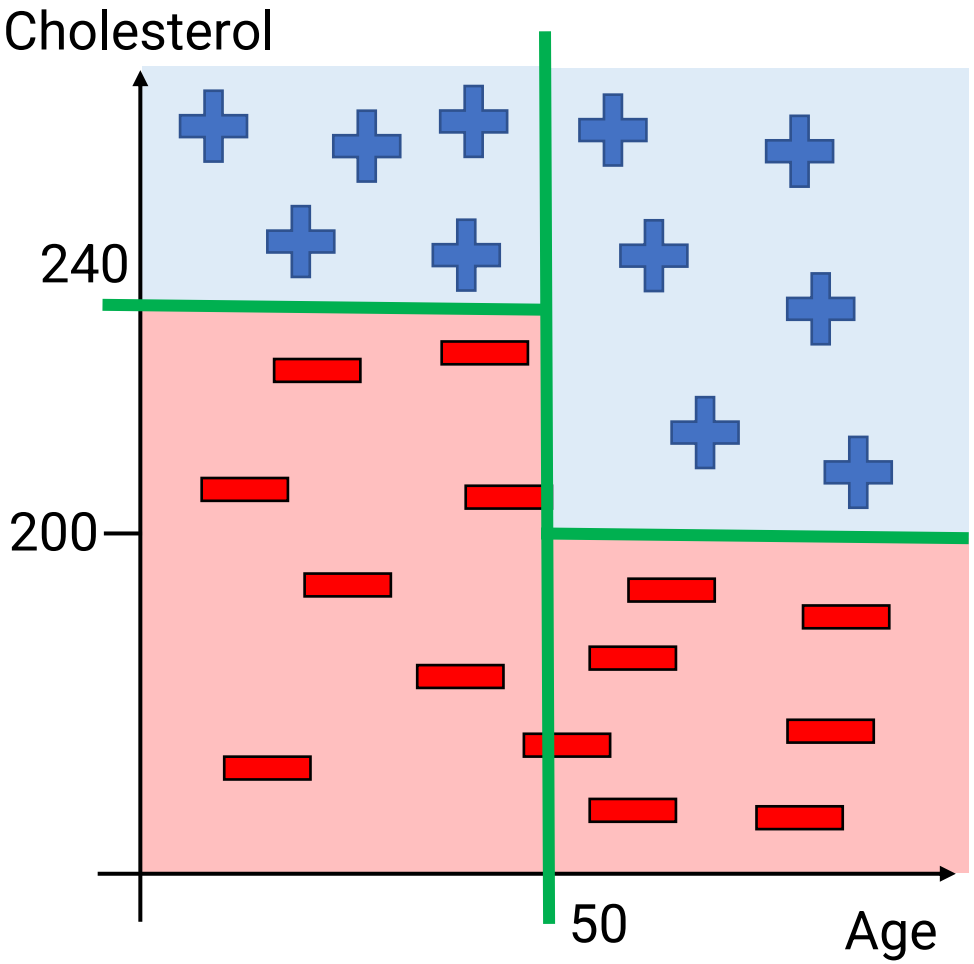
Modeling decision making

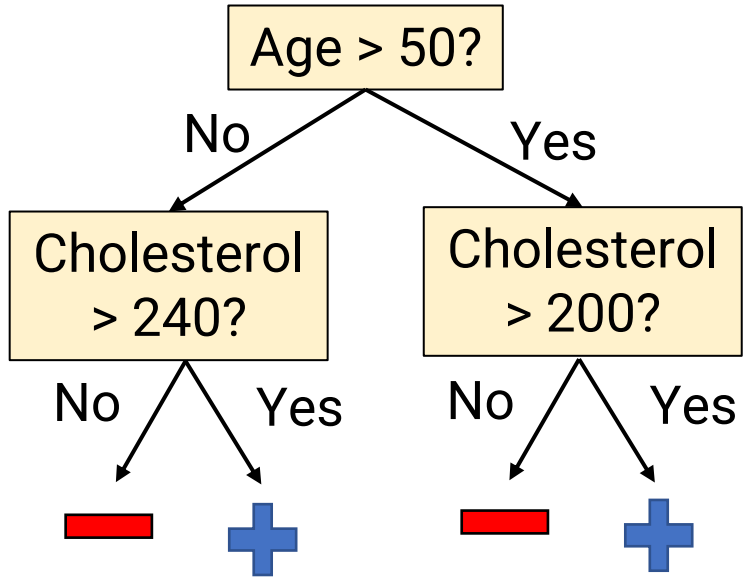
- Human experts make complex decisions and predictions every day
  - E.g., Given observations about a patient, what disease do they have?
- Doesn't really look like a linear function; more like a flow chart
- Can we build models that emulate the human decision-making process?



Decision Trees

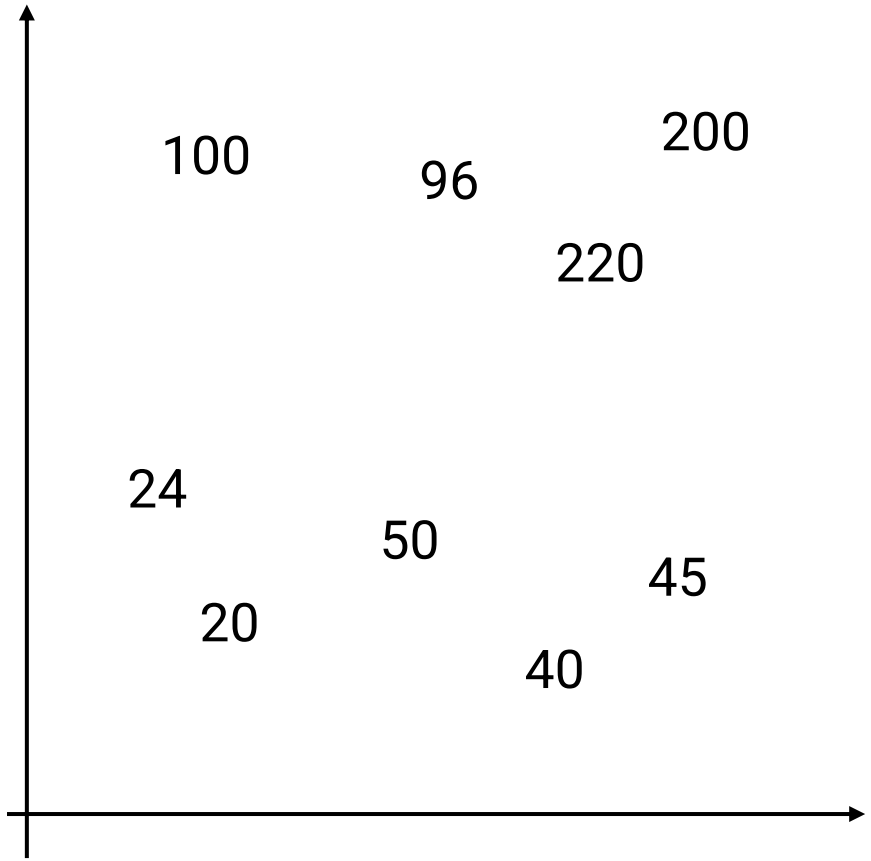
- At each node, split on one feature
- Remember the best output at each leaf node
  - Classification: Majority class
  - Regression: Mean within node
- Given new example, find which leaf node it belongs to and predict the associated output
- Interpretable!





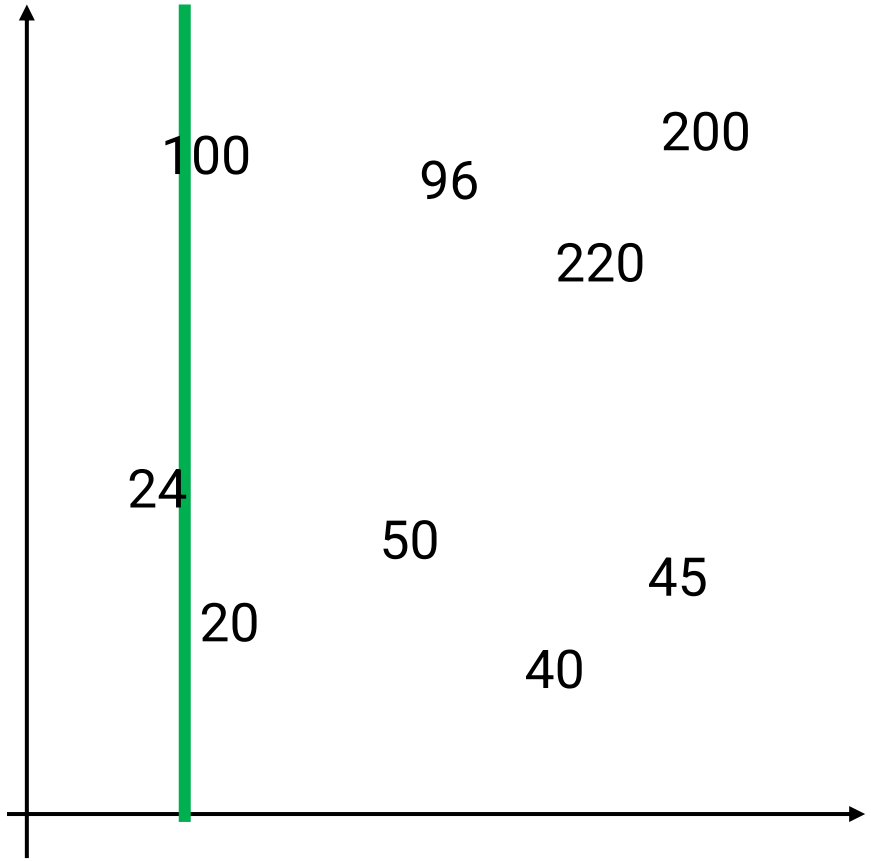
Learning Decision Trees for Regression

- At each node, decide:
  - Which feature to use
  - Which threshold to split on
- Strategy
  - Try each feature and all possible splits
  - Greedily choose split that minimizes error
    - For regression: Best prediction will be the mean on each side of the split, measure error of that relative to actual values



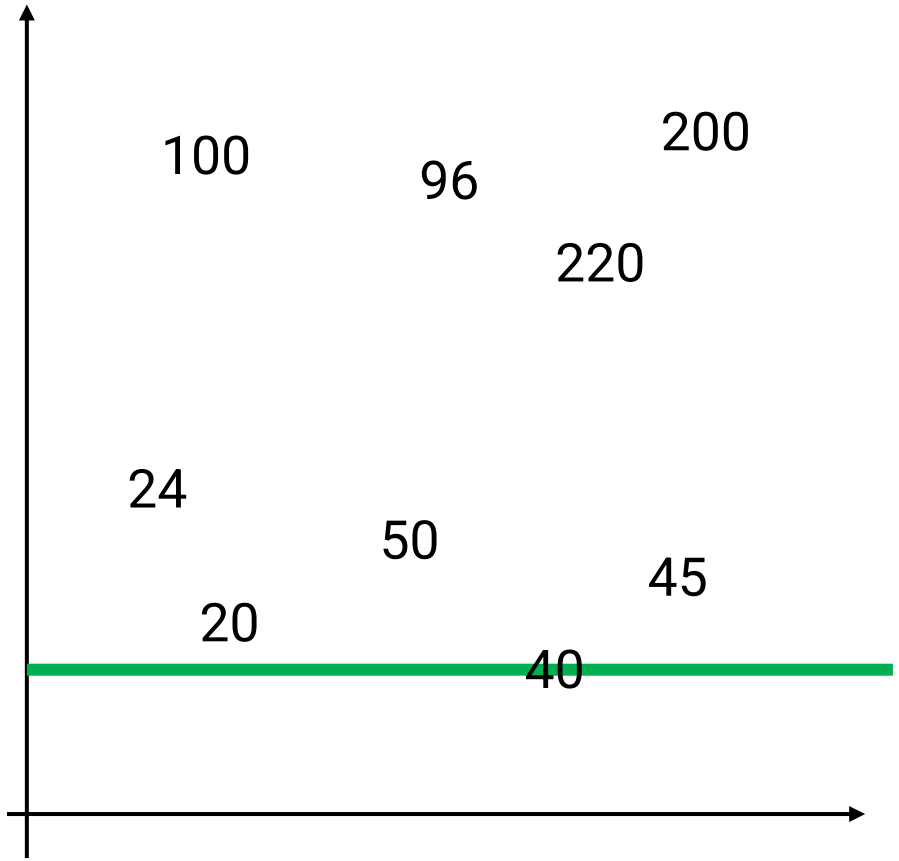
Learning Decision Trees for Regression

- At each node, decide:
  - Which feature to use
  - Which threshold to split on
- Strategy
  - Try each feature and all possible splits
  - Greedily choose split that minimizes error
    - For regression: Best prediction will be the mean on each side of the split, measure error of that relative to actual values



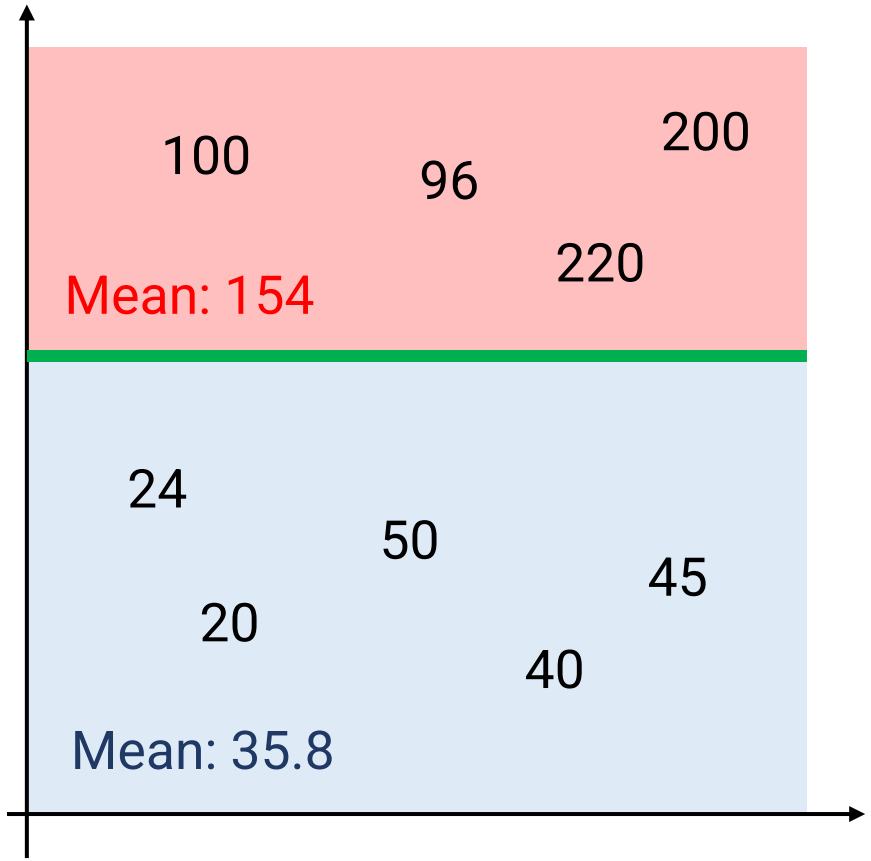
Learning Decision Trees for Regression

- At each node, decide:
  - Which feature to use
  - Which threshold to split on
- Strategy
  - Try each feature and all possible splits
  - Greedily choose split that minimizes error
    - For regression: Best prediction will be the mean on each side of the split, measure error of that relative to actual values



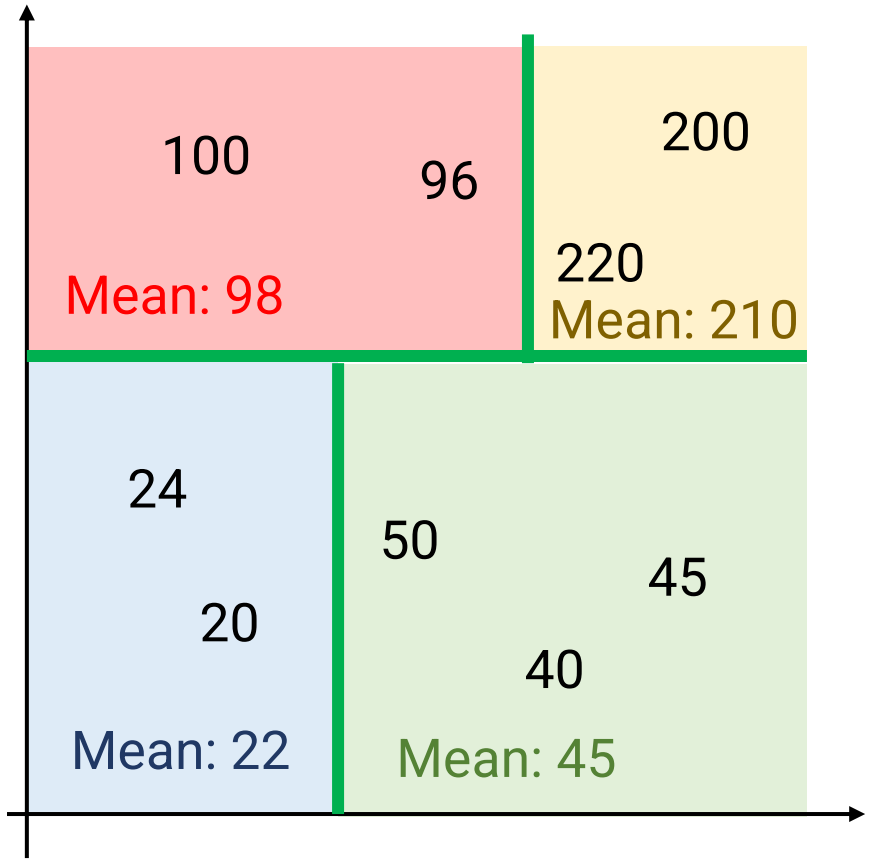
Learning Decision Trees for Regression

- At each node, decide:
  - Which feature to use
  - Which threshold to split on
- Strategy
  - Try each feature and all possible splits
  - Greedily choose split that minimizes error
    - For regression: Best prediction will be the mean on each side of the split, measure error of that relative to actual values



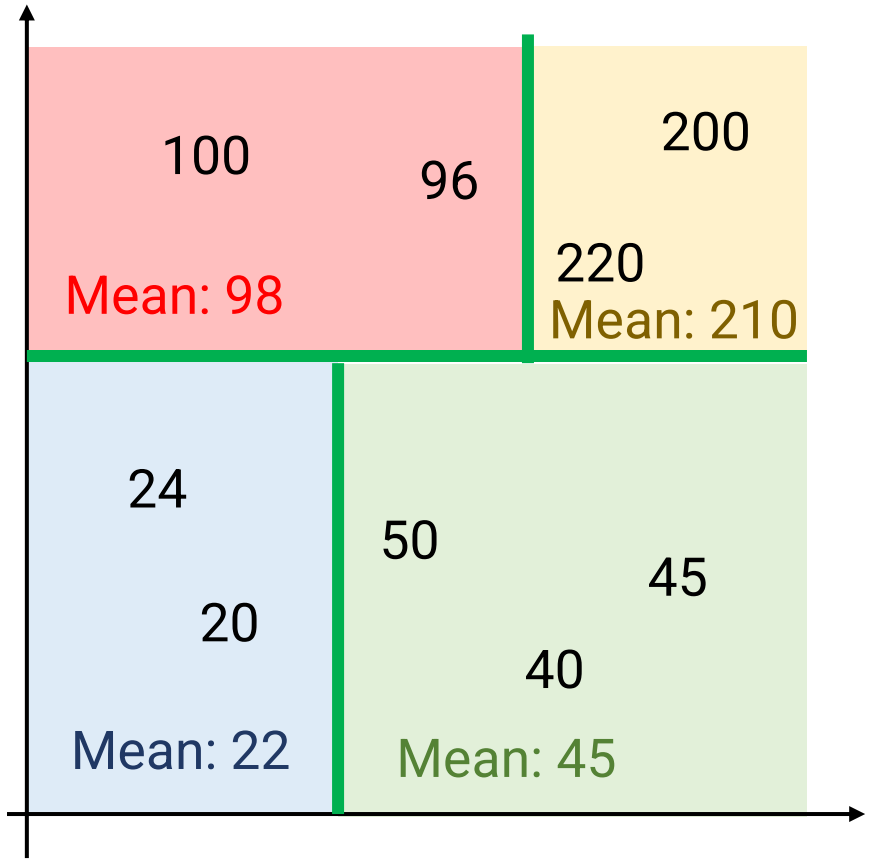
Learning Decision Trees for Regression

- At each node, decide:
  - Which feature to use
  - Which threshold to split on
- Strategy
  - Try each feature and all possible splits
  - Greedily choose split that minimizes error



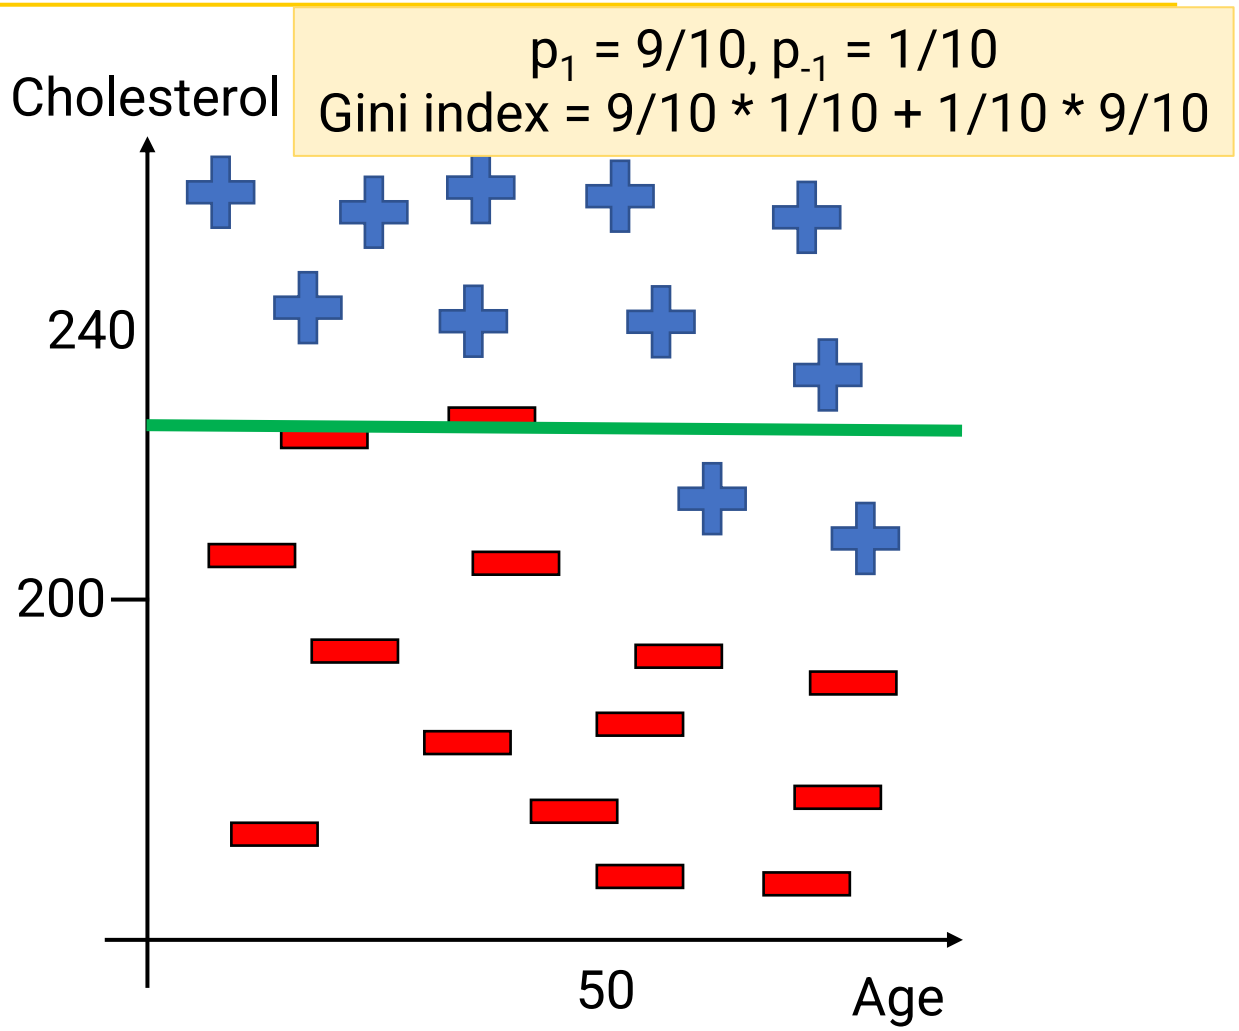
Learning Decision Trees for Regression

- When do we stop splitting?
  - If we split forever to nodes of size 1, we overfit
  - Heuristic stopping criteria
    - Minimum number of examples per node
    - Maximum depth of tree
  - Can go back afterwards and “prune” tree (i.e., merge nodes back together)



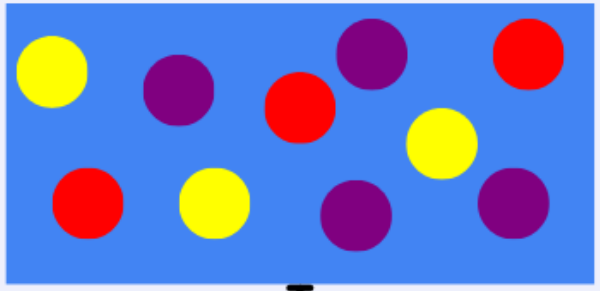
Learning decision trees for classification

- Basic idea is the same
- At leaf, predict the "majority label" in the node
- But how do we measure the goodness of a split?
  - Option 1: Accuracy of majority classifier
  - Option 2: Gini impurity
    - Formula: $\sum_{c=1}^{C} p_c(1 - p_c)$
    - p_c = Empirical probability of class c within the current node
    - Equals expected number of errors if you classify with the empirical distribution



Gini Impurity Example

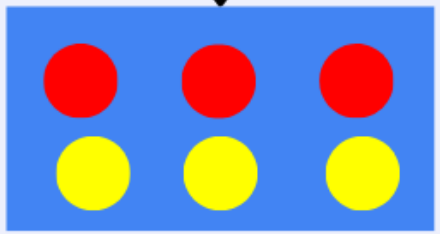
- Recall Gini Impurity Formula: $\sum_{c=1}^{C} p_c(1 - p_c)$



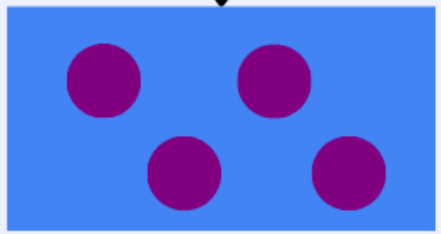
Initial Gini Impurity =
3/10 * 7/10 (apple)
+ 3/10 * 7/10 (banana)
+ 4/10 * 6/10 (grape)
= 0.66

Size = "Big"

Size = "Small"



Gini Impurity =
1/2 * 1/2 (apple)
+ 1/2 * 1/2 (banana)
+ 0 * 1 (grape)
= 0.5 ("less impure")

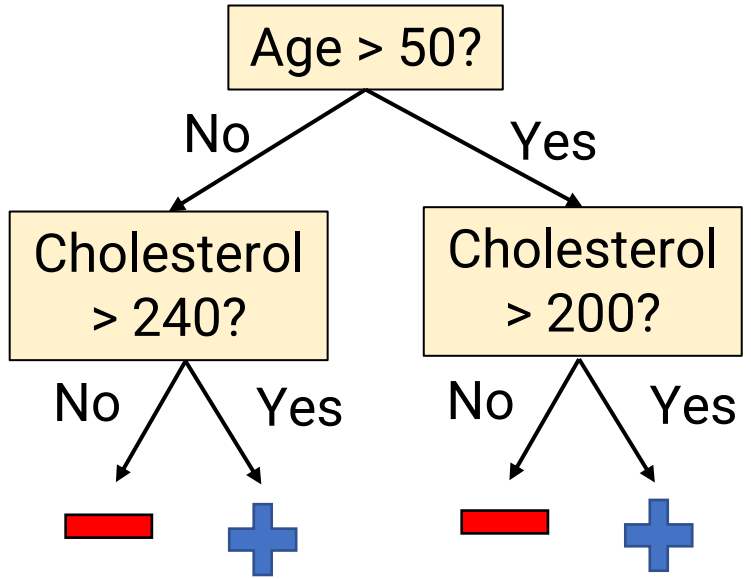


Gini Impurity =
0 * 1 (apple)
+ 0 * 1 (banana)
+ 1 * 0 (grape)
= 0 ("most pure")

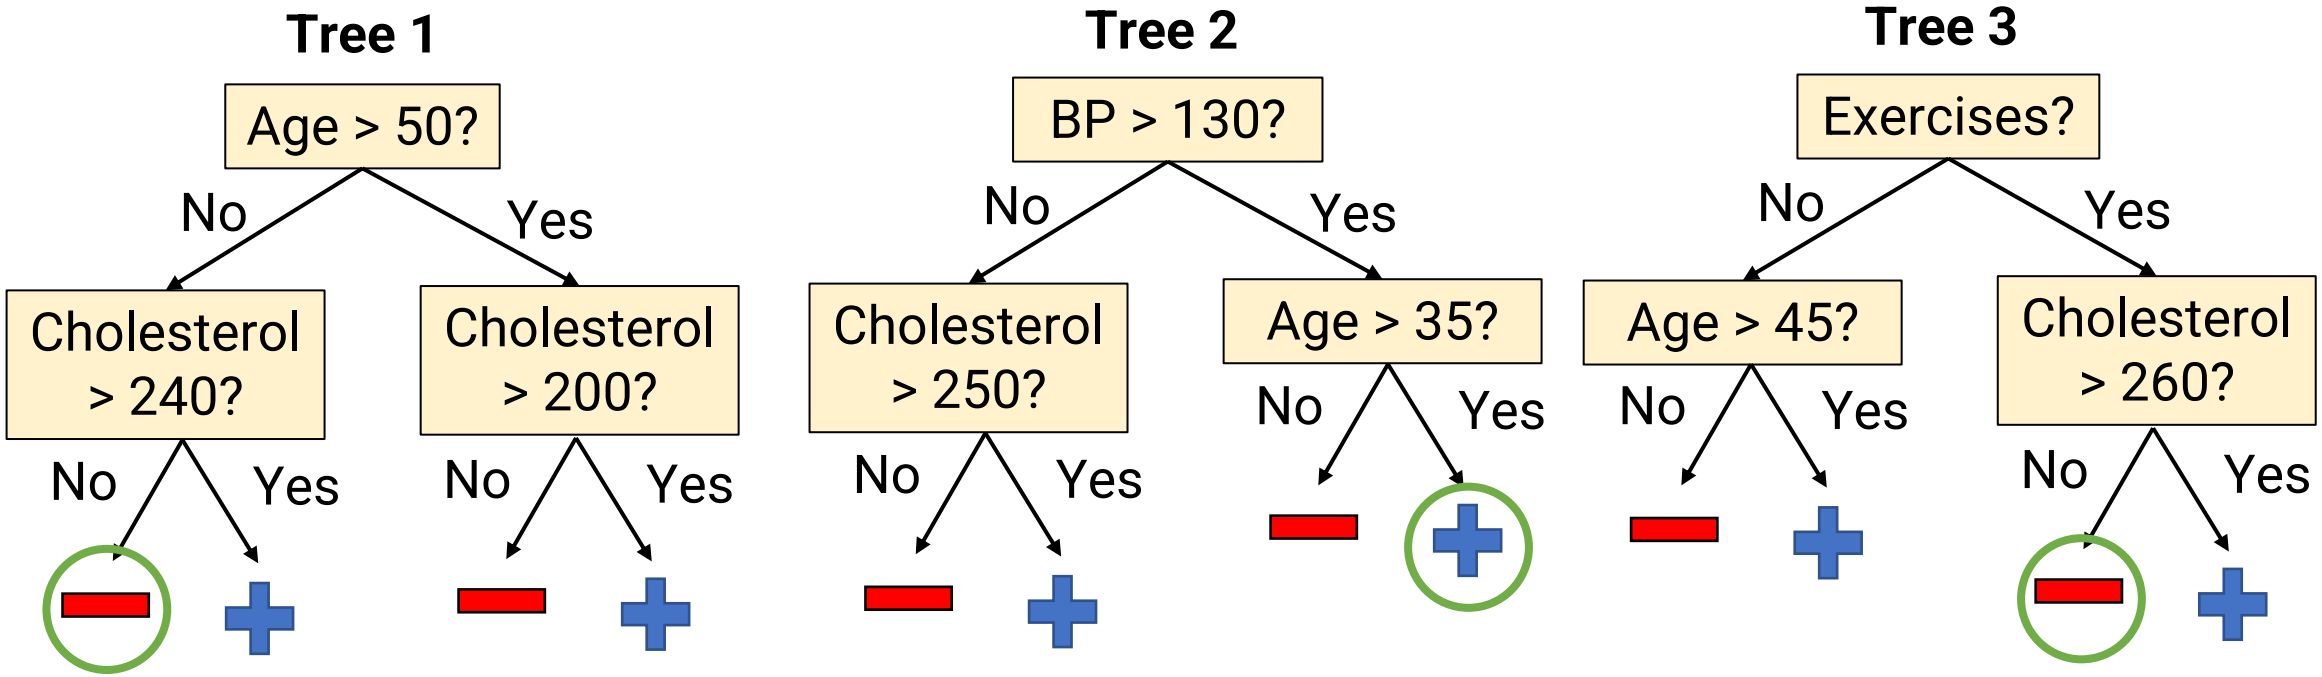
Overall score: Weighted average = 6/10 * 0.5 + 4/10 * 0 = 0.3

Handling Missing Features

- Some examples may be missing some features
  - E.g., For some patients, you didn't measure cholesterol level
  - What to do at a node where you split on cholesterol?
- Idea: Surrogate variables
  - During training, at each node, check which features act as **surrogates** of the feature you're using (i.e., lead to similar splits)
  - If original feature is missing, use a surrogate feature
  - E.g., If "blood pressure > 130" is correlated with "Cholesterol > 240", use blood pressure as surrogate for patients without cholesterol measurement

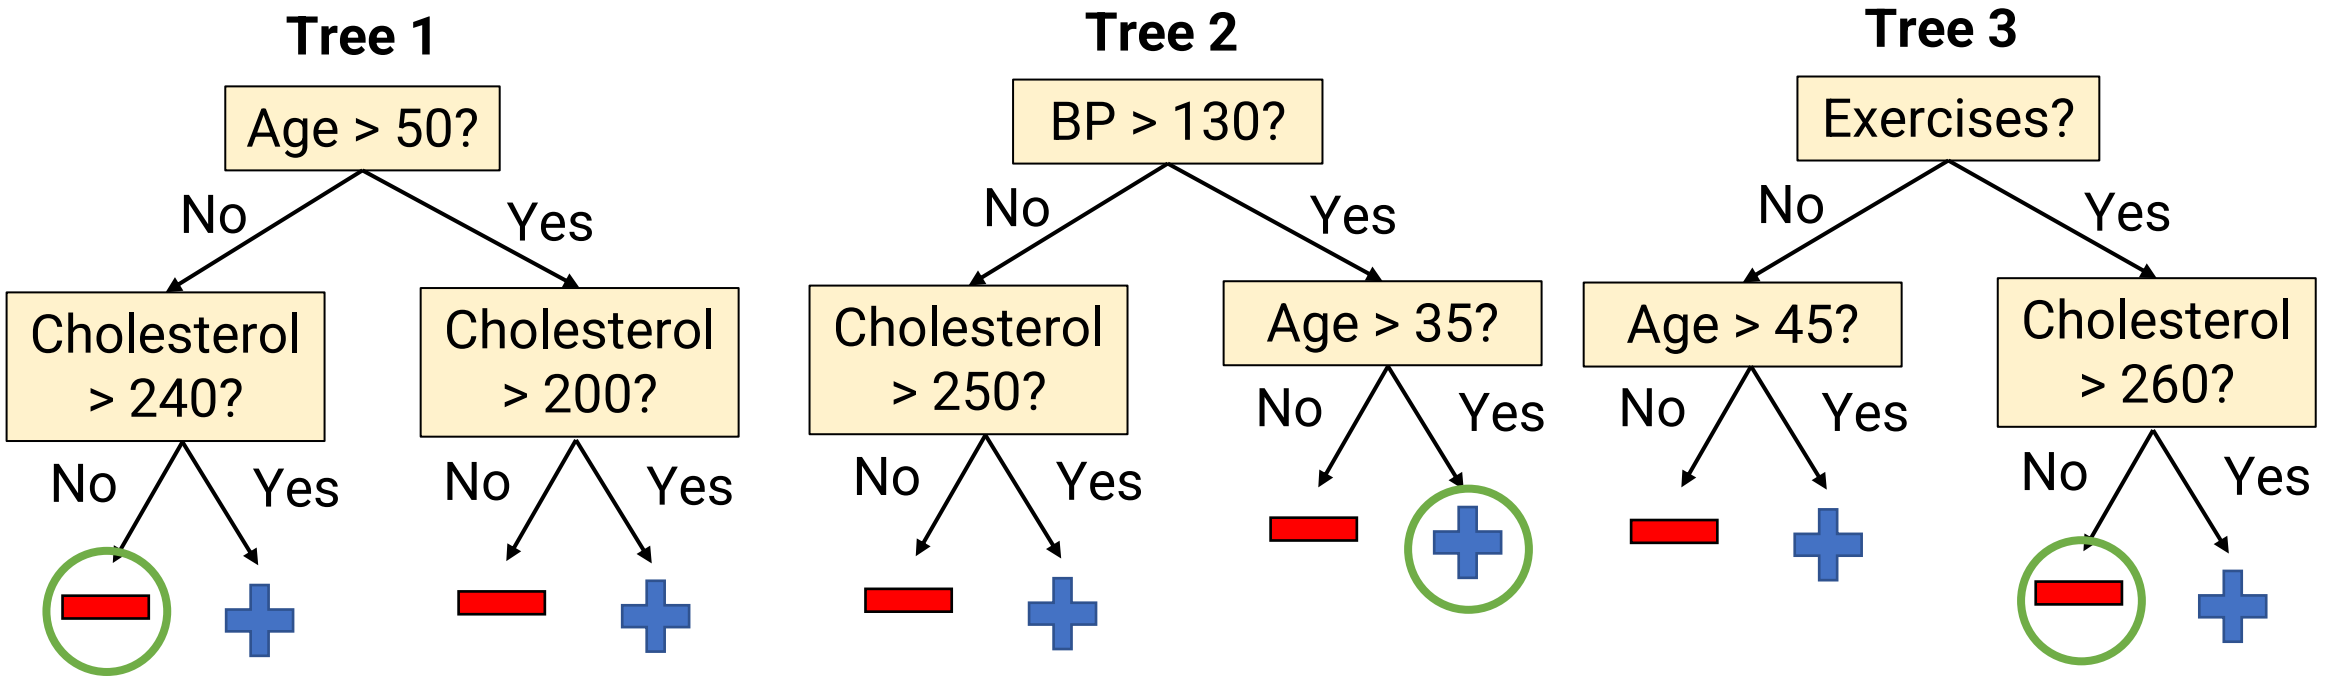


Ensembling



- Create an “ensemble” of multiple models (e.g., multiple trees)
- Make final prediction by averaging/majority vote

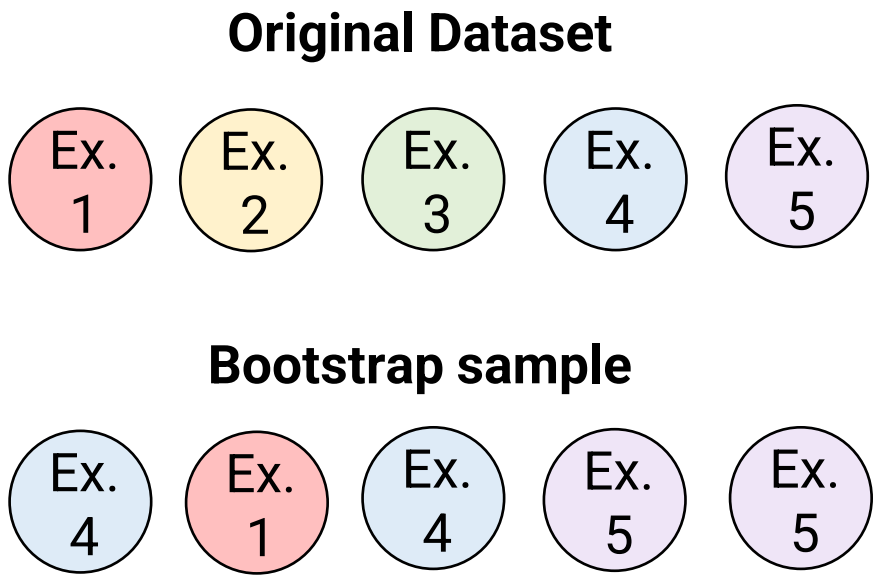
Ensembling and Trees



- An individual tree can capture complex patterns, but should not be too deep to avoid overfitting
- Thus it can only depend on a handful of features
- An ensemble of trees can leverage more features

Bagging

- How do you learn different trees from the same dataset?
- Idea: Randomly resample the dataset!
  - Given dataset with n examples, sample a new dataset of n examples **with replacement**
    - Also known as “Bootstrapping”
  - In expectation, each new dataset contains 63% of the original dataset, with some examples duplicated
  - Learn a tree on each resampled dataset

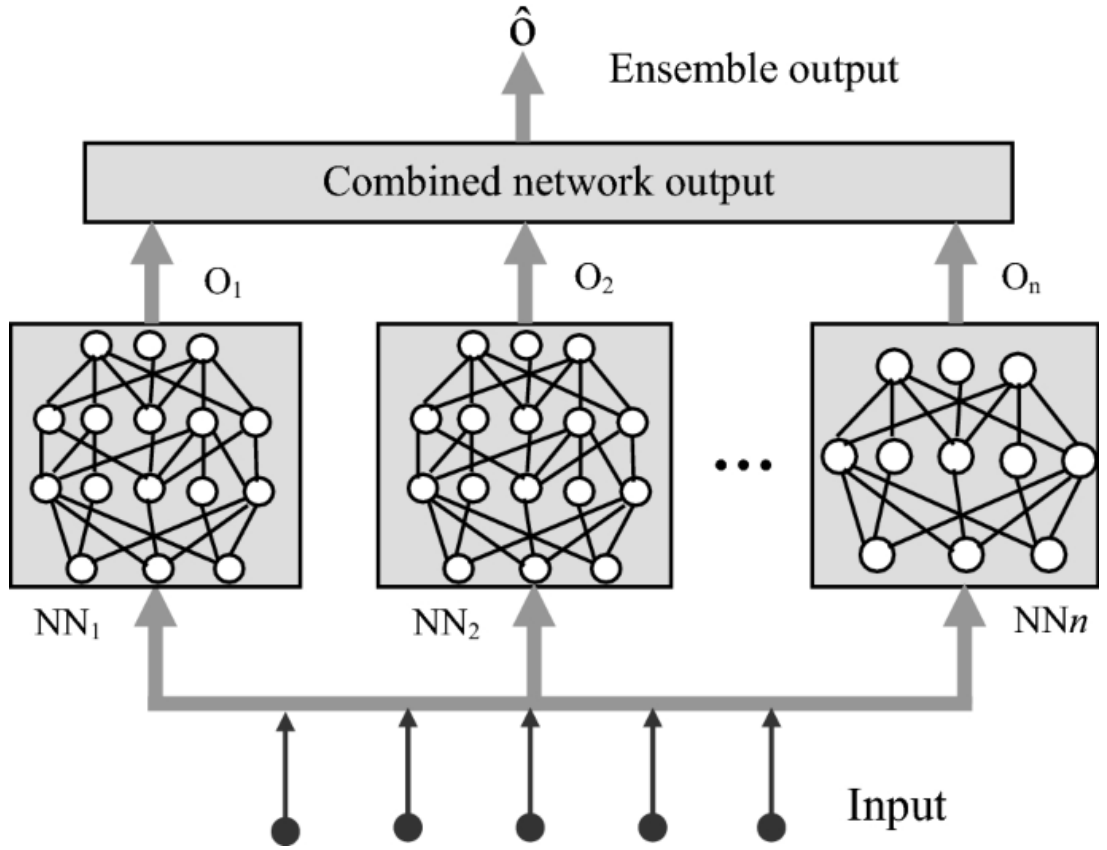


Random Forests

- Goal: Make the individual trees in the ensemble more different
  - Thus, all elements of the ensemble are complementary
- Simple strategy: Before each split, choose a random subset of features as candidates for splitting
  - Something like $\sqrt{d}$ features if *d* total features
  - Can even be randomly choosing 1 feature
- Very good general-purpose learners in practice!

Ensembles and neural networks

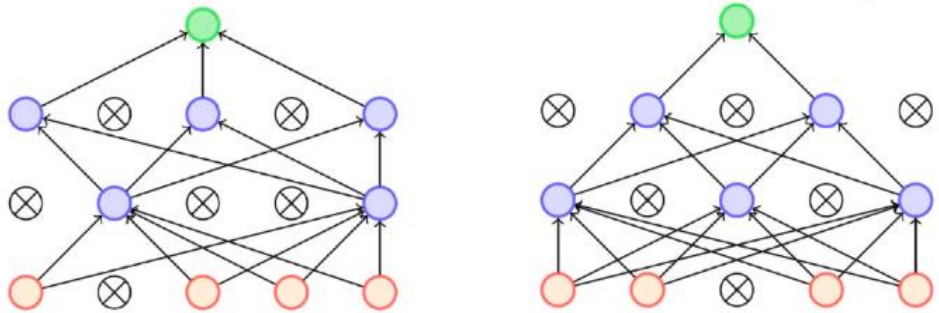
- Random Forest: Each member of ensemble differs due to random resampling of data & feature choice
- Neural Networks: Already have randomness
  - Initialization
  - Order of examples for SGD
  - Dropout
  - So, bagging is not necessary
- In practice: Very common to ensemble neural networks!
  - Compute vs. accuracy trade-off
  - Rumor: GPT-4 is an ensemble of 8 language models with 220 billion parameters each



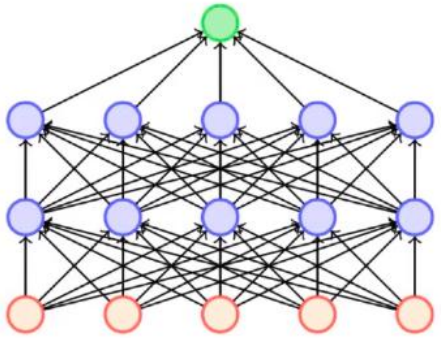
Dropout as an Ensemble

- Why does Dropout work? One explanation: **It learns a sort of ensemble**
- Training time
  - At each iteration, randomly drop out each neuron with probability *p*
  - Each iteration trains a weaker "subnetwork" instead of full network
- Test time
  - All neurons are active
  - Result is an average/ensemble of all the subnetworks
  - Note: Not exactly an ensemble in the usual sense because different subnetworks share parameters

Training time: Many "subnetworks"



Test time: Full network is average/ensemble of all subnetworks



Announcements

- Midterm exam: This Thursday March 13
  - Last name A-K: Go to DMC 100 (this room)
  - Last name L-Z: GO to SOS B4 (section room)
  - One 8.5” x 11” sheet of notes allowed, can be typed or handwritten
  - No other aids allowed
  - Please write in pen
  - Practice exams & lecture videos posted
  - All material up through end of last week is fair game (attention, but not decision trees)
- HW2 solutions posted
- Section Friday: First paper reading section (AlexNet)
- Final project
  - Project proposal grades should be released very soon
  - Will post list of mentors/graders assigned to each project, reach out with questions
  - Project Midterm Reports due Tuesday, April 1
